(57) ABSTRACT

A method is provided for controlling a three-phase, AC induction motor. Each phase of the AC induction motor is connected to an AC input source by a thyristor switch and a bypass contactor connected in parallel in order to provide voltage and current to the AC induction motor. The method includes the steps of sequentially firing pairs of thyristor switches at a predetermined initial gamma firing angle. A new gamma firing angle is calculated which is dependant upon the initial gamma firing angle. Thereafter, pairs of thyristor switches are fired at the new gamma firing angle. The new gamma firing angle and a new gamma firing angle is calculated. The process is repeated until the AC induction motor reaches its full operating speed.

METHOD AND CONTROLLING THE STARTING OF AN AC INDUCTION MOTOR WITH CLOSED LOOP CURRENT CONTROL

FIELD OF THE INVENTION

This invention relates to motor controls, and in particular, to a method of controlling the starting of an AC induction motor with a soft starter.

BACKGROUND AND SUMMARY OF THE **INVENTION**

There are two basic approaches for controlling the starting, stopping and speed of an AC induction motor. In a first approach, an adjustable frequency controller is interconnected to the AC induction motor. The adjustable frequency controller is comprised of an inverter which uses solid state switches to convery DC power to stepped waveform AC power. A waveform generator produces switching signals for the inverter under control of a microprocessor. While adjustable frequency controllers efficiently control the motor speed and the energy used by an AC induction motor, use of such types of controllers may be cost prohibitive. Further, since many applications of AC induction motors do not require sophisticated frequency and voltage control, an alternative to adjustable frequency controllers has been developed.

An alternate approach to the adjustable frequency controller is the soft starter. Soft starters operate using the principal of phase control whereby the line currents supplied to the AC induction motor are controlled by means of anti-parallel thyristor switches. Soft starters offer two major benefits for a user. First, use of a soft starter reduces the motor torque pulsation at startup of the AC induction motor which, in turn, results in less mechanical strain on the load. Second, use of a soft starter reduces the motor inrush current at startup of the AC induction motor which, in turn, places less stress on upstream electrical systems.

Typically, in a soft starter, the anti-parallel thyristor switches are provided in each supply line. These thyristor 40 switches in each supply line are fired to control the fraction of the half cycle over which current is conducted to the motor (known as the conduction period). The nonconducting period of each half cycle (known as the hold-off angle or the notch width) is visible as a notch in the voltage $_{45}$ waveform at each motor terminal. During this period, no current flows to the motor terminals. To end the nonconducting period, the thyristor switches in the supply line to the motor terminals are fired to restart their conduction. The conduction through the thyristor switches continues 50 until the current, once again, becomes zero at some point in the next half cycle and the thyristor switches reopen. According to the principles of phase control, by varying the duration of the non-conducting period, the voltage and current supplied to the AC induction motor may be con- 55 trolled.

Alternatively, with delta motors, the anti-parallel thyristor switches may be provided inside the delta. Positioning the anti-parallel thyristor switches within the delta allows for use of smaller electrical components since the phase current 60 magnitudes are less than the line current magnitudes.

Heretofore, in order to start an AC induction motor using a soft starter, two alternate types of control algorithms are used. In alpha control, the thyristor switches are sequentially fired at a certain angle, alpha (α), after the zero crossing 65 times of the corresponding phase voltages. In gamma control, the thyristor switches are sequentially fired at a

2

certain angle, gamma (γ), after the zero crossing times of the corresponding phase currents. It has been found that alpha control is more stable than gamma control in starting and bringing the AC induction motor to near operating speed because the zero crossings of the phase voltage are fixed while the zero crossings of the phase current move as the speed of the AC induction motor changes.

In addition, if gamma control is used during such period, greater current oscillation occurs which, in turn, leads to ¹⁰ greater torque oscillation. More specifically, torque oscillation when the motor is stalled or when accelerating up to speed generally is caused by a DC component in the motor current. One of the principle advantages of utilizing a soft starter is that by applying the voltage to the motor slowly, these DC offset currents can be eliminated. However, it is possible to re-introduce DC currents when using gamma control. For example, utilizing a constant gamma when the integral of the motor phase current for the positive half cycle differs from the integral of the motor phase current for the negative half cycle, produces a DC component. In fact, if a disturbance introduces a slight asymmetry in firing of the thyristor switches, gamma control will exhibit a tendency to amplify the asymmetry, since an early current zero crossing will cause the next thyristor firing to occur earlier with 25 respect to the terminal voltage. This effect is more pronounced when the soft starter is positioned inside the delta because the thyristor switches directly control phase voltage, that the current through the thyristor switches reflects the actual power of the motor (mostly inductive during acceleration), whereas line current control interposes a 30 degree angle between motor terminal voltage and line current being controlled.

Alternatively, gamma control is preferred once the motor has accelerated to the point where its speed is above the 35 breakdown speed, in other words, the speed at which the slope of the speed/torque curve is zero. This is due to the fact that the motor's torque production is a delayed function of speed. Therefore, as the motor accelerates to full speed, it overshoots before the electrical torque balances the mechanical load. Once the motor overshoots, the electrical torque eventually becomes negative and the speed undershoots its steady state value causing torque to become positive again. It may take several cycles of this oscillation to reach steady state when the terminal voltage on the motor is fixed. However, when gamma control is used, the changes in motor power factor caused by the speed changes result in changes in current zero cross time which, in turn, affect the firing point for the next half cycle of current. This results in slight cycle to cycle changes in terminal voltage. These changes have a damping effect on the oscillations described above. In fact, in many cases, the oscillations are damped within a complete cycle.

Therefore, it is a primary object and feature of the present invention to provide an improved method for controlling the starting of an AC induction motor.

It is a further object and feature of the present invention to provide a method for controlling the starting of an AC induction in a stable manner.

It is still a further object and feature of the present invention to provide a method for controlling the starting an AC induction motor which is simple and less expensive than prior art methods.

In accordance with the present invention, a method is provided for controlling a three-phase AC induction motor. Each phase of the induction motor is interconnected to an AC input source by a thyristor switch in order to provide

35

40

50

60

voltage and current to the AC induction motor. The method includes the steps of sequentially firing pairs of thyristor switches at a predetermined initial gamma firing angle after opening of the thyristor switches. Each thyristor switch opens in response to zero current therethrough. A new gamma firing angle is calculated which is dependant on the initial gamma firing angle. Pairs of thyristor switches are sequentially fired at the new gamma firing angle after opening of the thyristor switch.

Bypass contactors may be provided in parallel across 10 corresponding thyristor switches. The operating speed of the AC induction motor is monitored and the bypass contactors are closed in response to the AC induction motor operating at a predetermined operating speed. If the operating speed is less than the predetermined operating speed for the AC induction motor, the new gamma firing angle is provided as the initial gamma firing angle. Thereafter, a new gamma firing angle is calculated according to the expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is an integral of the motor current over a conduction time interval; and Ilim is a user selected pre-set current limit. The absolute value of the expression $k^* (I-I_{lim})$ is compared to a gamma limit prior to calculating the new gamma firing angle. The expression $k^*(I-I_{lim})$ is replaced with the gamma limit in the expression to calculate the new gamma firing angle if the absolute value of the expression $k^*(I-I_{lim})$ is greater than the gamma limit.

In accordance with a still further aspect of the present invention, a method is provided for controlling the voltage and current supplied to an AC motor. The AC motor is interconnected to an AC input source via a thyristor switch. The method includes the steps of initially firing the thyristor switch at a predetermined gamma firing angle after opening of the thyristor switch. The predetermined gamma firing angle is provided as an initial gamma firing angle and the thyristor switch is opened in response to zero supply current therethrough. A new gamma firing angle, dependant upon the initial gamma firing angle, is calculated and the thyristor switch is fired at the new gamma firing angle after occurrence of zero supply current therethrough. Thereafter, the new gamma firing angle is provided as the initial gamma firing angle.

It is contemplated to provide a bypass contactor in parallel to the thyristor switch. The operating speed of the AC motor is monitored and the bypass switch is closed in response to the AC motor operating at a predetermined operating speed. If the operating speed is less than the predetermined operating speed for the AC motor, a new gamma firing angle is calculated. The new gamma firing angle is according to the expression:

$$\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is an integral of the motor current over a conduction time interval; and I_{lim} is a user selected pre-set current limit. The absolute value of the expression $k^* (I-I_{lim})$ is compared to a gamma limit prior to calculating the new gamma firing angle. The expression $k^*(I-I_{lim})$ is replaced with the gamma limit in the expression to calculate the new gamma firing angle if the absolute value of the expression $k^*(I-I_{lim})$ is greater than the gamma limit.

In accordance with a still further aspect of the present 65 invention, a method is provided for controlling a threephase, AC induction motor. Each phase of the AC induction

1

motor is interconnected to an AC source by a thyristor switch and a bypass contactor connected in parallel in order to provide voltage and current to the AC induction motor. The method includes the steps of sequentially firing pairs of thyristor switches at a predetermined initial gamma firing angle after opening of the thyristor switches. Each thyristor switch opens in response to zero supply current therethrough. A new gamma firing angle is calculated which is dependant upon the difference between an integral of motor current over a conduction time interval and a user selected pre-set current limit. Pairs of thyristor switches are fired at the new gamma firing angle after opening of the thyristor switches. The operating speed of the AC induction motor is monitored and if the operating speed is less than a predetermined operating speed, the new gamma firing angle is provided as the initial gamma firing angle, and a new gamma firing angle is calculated. The new gamma firing angle is according to the expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

 $_{20}$ wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is the integral of the motor current over a conduction time interval; and I_{lim} is the user selected pre-set current limit. The absolute value of the expression k $*(I-I_{lim})$ is compared to a gamma limit prior to calculating the new gamma firing angle. The expres-25 sion $k^*(I-I_{lim})$ is replaced with the gamma limit in the expression to calculate the new gamma firing angle if the absolute value of the expression $k^*(I-I_{lim})$ is greater than the gamma limit. It is contemplated to close the bypass contactors in response to the AC motor operating at the predeter-30 mined operating speed.

BRIEF DESCRIPTION OF THE DRAWINGS

The drawings furnished herewith illustrate a preferred construction of the present invention in which the above advantages and features are clearly disclosed as well as others which will be readily understood from the following description of the illustrated embodiment.

In the drawings:

FIG. 1 is a schematic view of a motor system for executing a method in accordance with the present invention:

FIGS. 2a and 2b are graphical representations of the voltage across and the current through a pair of anti-parallel $_{45}$ thyristor switches in FIG. 1 as a function of time;

FIG. 3 is a flow chart of computer executable instructions for executing a first embodiment of the method of the present invention:

FIG. 4 is a flow chart of computer executable instructions for executing a second embodiment of the method of the present invention;

FIG. 5 is a flow chart of computer executable instructions for executing a third embodiment of the method of the present invention;

55 FIG. 6 is a schematic view of a motor system for executing an alternate method in correspondence with the present invention;

FIGS. 7a and 7b are graphical representations of the voltage across and the current through a pair of anti-parallel thyristor switches in FIG. 6 as a function of time; and

FIG. 8 is a flow chart of computer executable instructions for executing a fourth embodiment of the method of the present invention.

DETAILED DESCRIPTION OF THE DRAWINGS

Referring to FIG. 1, a motor system for executing a method in accordance with the present invention is generally

designated by the reference number 10. Motor control system 10 includes an AC induction motor 12 having terminals 13a-f. Terminals 13a, 13b and 13c of AC induction motor 12 are coupled to a three phase AC source 18 by supply lines 16*a*, 16*b* and 16*c*. As is conventional, AC source 18 provides line voltages V_A , V_B and V_C and line currents I_A , I_B and I_C through corresponding supply lines 16a, 16b and 16c to AC induction motor 12.

In the preferred embodiment, AC induction motor 12 is a delta motor and soft starter 14 is applied in series with 10 windings 20a, 20b and 20c of AC induction motor 12. Soft starter 14 includes anti-parallel silicon controlled rectifiers (SCRs) or thyristor switches 22a, 22b, and 22c which are connected in series with corresponding windings 20a, 20b and 20c of AC induction motor 12. Each thyristor switch 15 22a, 22b and 22c consists of a pair of inversely connected SCRs used to control the phase voltages $\mathbf{V}_a,\,\mathbf{V}_b$ and \mathbf{V}_c across and phase currents I_a , I_b and I_c through windings 20*a*, 20b and 20c of AC induction motor 12. Bypass contactors 24a, 24b and 24c are connected in parallel to corresponding thyristor switches 22a, 22b and 22c, respectively, for reasons 20 hereinafter described.

The phase voltages V_a , V_b and V_c across and phase currents I_a , I_b and I_c through windings **20***a*, **20***b* and **20***c* of AC induction motor 12 are identical but for being 120° out of phase with each other. Further, phase currents I_a , I_b and 25 I_c lag the phase voltages V_a , V_b and V_c by an angle θ corresponding to the power factor of AC induction motor 12. By way of example, referring to FIGS. 2a and 2b, phase voltage V_a across winding 20a is compared to the phase current I_a and terminal voltage V_T which is the difference in potential between terminals 13d and 13b of AC induction motor 12. As is known, the waveform of terminal voltage V_T is sinusoidal. The phase voltage V_a is generally identical to the terminal voltage V_T except during a small, non-conducting time or notch having a duration γ which is 35 introduced into each half cycle of terminal voltage V_T. Notch γ is introduced into terminal voltage V_T each time phase current I_a falls to zero. Phase current I_a remains at zero until the end of notch y at which time phase current I_a continues a pulsating waveform. 40

The phase current I_a is controlled by the duration of notch γ . During notch γ , thyristor switch 22a which interconnects motor terminal 13a and winding 20a operates as an open circuit so that instead of observing sinusoidal terminal voltage V_T between motor terminals 13d and 13b, an inter-45 nal motor generated back EMF voltage may be seen. The back EMF voltage is generally equal to the terminal voltage VT minus the voltage drop V_{ad} across thyristor switch 22a.

In accordance with the present invention, four alternate approaches for starting and bringing the AC induction motor 50 to its full operating speed are provided. Referring to FIG. 3, in the first approach generally designated by the reference numeral 28, thyristor switches 22a, 22b and 22c are fired (turned on) after a user selected alpha firing angle α after the initial zero voltage crosses of corresponding terminal volt-55 ages V_T . In the preferred embodiment, the user selected alpha firing angle α is generally equally to 135°, block **30**. However, other values for the user selected alpha firing angle α are contemplated as being within the scope of the present invention.

Thereafter, the alpha firing angle α is reduced by a predetermined amount and thyristor switches 22a, 22b and 22c are fired again at the reduced alpha firing angle α after the next zero voltage crosses of corresponding terminal voltages V_{T} . In the preferred embodiment, the reduced or 65 new alpha firing angle is calculated according to the expression:

$\alpha_i = -16 * t + 135$

wherein α_i is the new alpha firing angle; "-16" and "135" are constants which may be varied according to the application; and t is the elapsed time from the initial firing of thyristor switches 22a, 22b and 22c, block 32. The process is repeated for a predetermined period of time, e.g. 2.5 seconds, block 34.

Upon completion of the predetermined period of time, the alpha firing angle α is maintained at a selected alpha firing angle α , block 36, and thyristor switches 22*a*, 22*b* and 22*c* are subsequently fired at such alpha firing angle α after each zero voltage crosses of corresponding terminal voltages V_T for a second predetermined time period, e.g. 8 seconds, block 38. Upon completion of the second predetermined time period, the control methodology is changed from alpha control to gamma control, block 40.

In gamma control, the phase currents I_a , I_b and I_c of AC induction motor 12 are maintained by maintaining the half cycle time of thyristor switches 22a, 22b and 22c such that the duration of notch γ is maintained until AC induction motor 12 is at full operating speed, block 42. In the preferred embodiment, the duration of notch γ is maintained at 10°, block 40, but other angles are contemplated as being within the scope of the present invention. Full operating speed of AC induction motor 12 may be determined in any conventional manner. For example, by maintaining the phase currents I_a , I_b and I_c of AC induction motor 12 at a predetermined level over a predetermined period of time, the angle θ , FIGS. 2a and 2b, of the power factor of AC induction motor 12 is reduced and the back EMF voltages approach the terminal voltages V_T . Once the back EMF voltages exceed a predetermined value, AC induction motor 12 is at full operating speed and corresponding bypass contactors 24a, 24b and 24c are sequentially closed, block 44, such that windings 20a, 20b and 20c are connected directly between corresponding pairs of motor terminals 13a, 13b and 13c.

Referring to FIG. 4, in the second approach generally designated by the reference numeral 46, thyristor switches 22a, 22b and 22c are fired after a user selected alpha firing angle α , i.e. 135°, block 48, after the initial zero voltage crosses of corresponding terminal voltages V_T . Thereafter, the alpha firing angle α is reduced and thyristor switches 22a, 22b and 22c are fired again at the reduced alpha firing angle α after the next zero voltage crosses of corresponding terminal voltages V_T . As heretofore described, in the preferred embodiment, the reduced or new alpha firing angle is calculated according to the expression:

 $\alpha_i = -16 * t + 135$

60

wherein α_i is the new alpha firing angle; "-16" and "135" are constants which may be varied according to the application; and t is the elapsed time from the initial firing of thyristor switches 22a, 22b and 22c, block 50. The process is repeated for a predetermined period of time, e.g. 2.5 seconds, block 52.

Upon completion of the predetermined period of time, the alpha firing angle α is maintained, block 54, at a selected alpha firing angle α , e.g. 95°, and thyristor switches 22*a*, 22*b* and 22c are subsequently fired at such alpha firing angle α after each zero voltage crosses of corresponding terminal voltages $V_{T_{1}}$

As thyristor switches 22a, 22b and 22c are subsequently fired at alpha firing angle α , the current limit I_{lim} of AC induction motor 12 is determined. In the preferred embodiment, current limit is calculated according to the expression:

wherein I_{lim} is the current limit, FT is the initial firing time of the thyristor switches; NST is the next stopping time of the thyristor switches; i(t) is the instantaneous phase. current; and, in the preferred embodiment, 2.5 seconds <t<3.5 seconds, block 54.

7

Thereafter, the phase currents I_a , I_b and I_c of AC induction motor 12 are determined according to the expression:

$$I = \int_{FT}^{NST} |i(t)| dt$$

 $I_{lim} = \int_{FT}^{NST} |i(t)| dt$

wherein I is the integral of the motor current over the previous conduction interval; FT is the initial firing time of the thyristor switches; NST is the next stopping time of the thyristor switches; and i(t) is the instanteous phase current, 15 block 56.

As long as the instantaneous phase currents I_a , I_b and I_c of AC induction motor 12 are greater than a predetermined percentage of the current limit I_{lim} of AC induction motor 12, e.g. $0.8*I_{lim}$ the process is repeated and thyristor 20 switches 22a, 22b and 22c are fired again at the selected alpha firing angle α , block **58**. If the phase currents I_a, I_b and I_c of AC induction motor 12 drop below the predetermined percentage of the current limit I_{lim} , the control methodology is changed from alpha control to gamma control, block 60.

As heretofore described with respect to the first approach, in gamma control, the phase currents I_a , I_b and I_c of AC induction motor 12 are maintained by maintaining the half cycle time of thyristor switches 22a, 22b and 22c such that the duration of notch γ is maintained until AC induction 30 motor 12 is at full operating speed, block 62. In the preferred embodiment, the duration of notch γ is maintained at 10°, block 60, but other angles are contemplated as being within the scope of the present invention. Upon a determination that the AC induction motor **12** is at full operating speed, bypass contactors 24a, 24b and 24c are sequentially closed, block 64, such that windings 20a, 20b and 20c are connected directly between corresponding pairs of motor terminals 13a, 13b and 13c.

Referring to FIG. 5, in the third approach generally designated by the reference numeral 66, thyristor switches 22a, 22b and 22c are initially fired at a user selected alpha firing angle a, i.e. 135°, block 68, after the initial zero voltage crosses of corresponding terminal voltages V_T . Thereafter, a new alpha firing angle α is calculated based 45 upon the error between the integration of the phase currents I_a , I_b and I_c of AC induction motor 12 and the current limit I_{lim} of AC induction motor 12, block 70. In the preferred embodiment, current limit I_{lim} is a known constant, block **68**, and the phase currents I_a , I_b and I_c of AC induction motor 12 50 are determined according to the expression:

 $I = \int_{FT}^{NST} i(t) |dt|$

wherein I is the integral of the motor current over the 55 previous conduction interval; FT is the initial firing time of the thyristor switches; NST is the next stopping time of the thyristor switches; and i(t) is the instantaneous phase current, block 70.

The new alpha firing angle is reduced according to the 60 expression:

 $\alpha_i{=}\alpha_{i{-}1}{+}K^*(I{-}I_{lim})$

wherein α_i is the new alpha firing angle; α_{i-1} , is the prior alpha firing angle; k is a proportional gain; I is the integral 65 of the motor current over the various conduction interval; and I_{iim} is a user selected pre-set current limit, block 72. To

8

maintain the stability of AC induction motor 12, it is contemplated that the maximum absolute value of the expression $k^*(I-I_{lim})$ be limited to 0.25°, block 72. Thyristor switches 22a, 22b and 22c are fired again at the new alpha firing angle γ_i after the next zero voltage crosses of corresponding terminal voltages V_T and the process is repeated until the phase currents I_a , I_b and I_c of AC induction motor 12 drop below a predetermined percentage of the current limit I_{lim} , e.g. $0.8*I_{lim}$, indicating that the AC induction 10 motor 12 is approaching full operating speed, block 74. Once the phase currents I_a , I_b and I_c of AC induction motor 12 drop below the predetermined percentage of the current limit I_{lim} , the control methodology is changed from alpha control to gamma control, block 76.

In gamma control, gamma is initialized, block 77, according to the expression:

 $\gamma_{i-1} = 2 * \alpha_i - 180^{\circ}$

wherein γ_{i-1} is the initial gamma firing angle and α_i is the new alpha firing angle as heretofore described; and the phase currents I_a , I_b and I_c are gradually increased over a period of time. In order to increase the phase currents I_a , I_b and I_c applied to AC induction motor 12, the half cycle time of thyristor switches 22a, 22b and 22c must be increased. In 25 order to gradually increase the half cycle time of the thyristor switches 22*a*, 22*b* and 22*c*, the duration of notch γ in the voltage waveforms V_T is reduced with each subsequent firing thyristor switches 22a, 22b and 22c according to expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is the integral 35 of the motor current over the previous conduction interval; and I_{lim} is a user selected pre-set current limit, block 78. To maintain the stability of AC induction motor 12, it is contemplated that the maximum absolute value of the expression k*(I-I_{lim}) be limited to 0.25°, block 78. Thyristor switches 22a, 22b and 22c are fired again at the new gamma 40 firing angle γ_i after the next zero current crosses of corresponding phase currents I_a , I_b and I_c and the process is repeated until the AC induction motor 12 is at full operating speed, block 80. Once the AC induction motor 12 is at full operating speed, bypass contactors 24a, 24b and 24c are sequentially closed, block 82, such that windings 20a, 20b and **20***c* are connected directly between corresponding pairs of motor terminals 13a, 13b and 13c.

In order for soft starter 14 to function as heretofore described, it is contemplated that a microprocessor (not pictured) carry out a number of predetermined functions which are incorporated into computer executable instructions, FIGS. 3-5. It should be understood that while these functions are described as being implemented in software, it is contemplated that the functions could be implemented in discreet solid state hardware, as well as, the combination of solid state hardware and software.

It is contemplated that in order to effectuate the methods of the present invention, the microprocessor will include a plurality of inputs corresponding to selected parameters heretofore described. For example, such inputs include line voltages V_A , V_B and V_C ; line currents I_A , I_B and I_C , phase voltages V_a , V_b and V_c ; and phase currents I_a , I_b and I_c . Further, it is contemplated that the microprocessor generate a plurality of output signals which correspond to selected instructions heretofore described. For example, referring back to FIG. 1,, microprocessor generates firing signals S_A ,

15

 S_B and S_C to fire corresponding thyristor switches 22a, 22b, and 22c, respectively, at appropriate times, as heretofore described. Similarly, microprocessor generates firing signals B_A , B_B and B_C to close corresponding bypass contactors 24a, 24b, and 24c, respectively, at appropriate times, as heretofore described.

Referring to FIG. 6, an alternate motor control system in accordance with the present invention is generally designated by the reference number 90. Motor control system 90 includes an AC induction motor 96 coupled to an AC source 10 98, as hereinafter described.

As is conventional, AC induction motor 96 has three windings. Each winding of AC induction motor 96 is operatively connected to a corresponding supply line 100, 102 and 104 from AC source 98 at motor terminals 106, 108 and 110, respectively. Anti-parallel silicon controlled rectifiers (SCRs) or thyristor switches 112, 114, and 116 are also provided. Each thyristor switch 112, 114 and 116 consists of a pair of inversely connected SCRs used to control the voltage on, and the current through, an associated supply 20 line 100, 102 and 104, respectively, which, in turn, alters the current supplied to and the voltage at motor terminals 106, 108, and 1.10, respectively, of AC induction motor 96.

The terminal voltages V_{T1} at motor terminals 106, 108 and 110 of AC induction motor 96, the supply voltages V_{A1} , 25 V_{B1} and V_{C1} , and the line currents I_{A1} , I_{B1} and I_{C1} are identical but for being 120° out of phase with each other. By way of example, referring to FIGS. 6 and 7a-7b, terminal voltage V_{AT1} at motor terminal 106 is compared to the line current I_{A1} and the supply voltage V_{A1} from AC source 98. 30 As is known, the waveform of supply voltage V_{A1} is sinusoidal. When controlled by phase control, the terminal voltage V_{AT1} is generally identical to the supply voltage V_{A1} except during a small non-conducting time or notch having a duration γ which is introduced into each half cycle of 35 supply voltage V_{A1} . Notch γ is introduced into the supply voltage V_{A1} each time line current I_{A1} falls to zero. Line current I_{A1} remains at zero until the end of notch γ at which time line current I_{A1} continues a pulsating waveform.

The supply line current I_{A1} is controlled by the duration 40 of notch γ . During notch γ , thyristor switch 112 which interconnects motor terminal 106 to AC source 98 operates as an open circuit so that instead of observing sinusoidal supply voltage V_{A1} at motor terminal 106, an internal motor generated back EMF voltage may be seen. The back EMF 45 voltage is generally equal to the source voltage V_{A1} minus the voltage drop V_{AD1} across thyristor switch 112.

There are various approaches to bring AC induction motor 96 to its operating speed. In the first approach, line currents I_{A1} , I_{B1} and I_{C1} are gradually increased over a period of time. 50 In order to increase the line currents I_{A1} , I_{B1} and I_{C1} applied to AC induction motor 96, the conduction period of thyristor switches 112, 114 and 116 is increased. As the conduction period of the thyristor switches 112, 114 and 116 is gradually increased during each half cycle, the duration of notch γ in 55 the voltage waveforms at motor terminals 106, 108 and 110 is reduced. In addition, as the conduction period of thyristor switches 112, 114 and 116 is gradually increased and the AC induction motor 96 approaches operating speed, the back EMF voltages at motor terminals 106, 108, and 110 increase. 60 It is contemplated that once the back EMF voltages at motor terminals 106, 108 and 110 exceed a predetermined value, the AC induction motor 96 is considered operating at its full operating speed. If the motor current has fallen to the FLA for the AC induction motor 96, bypass contactors 120, 122, 65 and 124, which are connected in parallel to corresponding thyristor switches 112, 114, and I16, respectively, are

sequentially closed. With bypass contactors 120, 122 and 124 closed, motor terminal 106 of AC induction motor 96 is connected directly to AC source 98 through supply line 100, motor terminal 108 of AC induction motor 96 is connected directly AC source 98 through supply line 102, and motor terminal **110** of AC induction motor **96** is connected directly to AC source 98 through supply line 104.

Alternatively, AC induction motor 96 may be brought to operating speed by providing constant current thereto. As is known, line current I_{A1} , I_{B1} and I_{C1} lags the supply voltage V_{A1} , V_{B1} and V_{C1} by an angle θ corresponding to the power factor of AC induction motor 96. The line currents I_{A1} , I_{B1} and I_{C1} to AC induction motor 16 are maintained by maintaining the conduction period of thyristor switches 112, 114 and 116 such that the duration of notch γ is maintained. By maintaining the line currents I_{A1} , I_{B1} and I_{C1} to AC induction motor 96 at a predetermined level over a predetermined period of time, the angle θ of the power factor of AC induction motor 16 reduces as AC induction motor 96 accelerates and the back EMF voltages at motor terminals 106, 108 and 110 approaches corresponding source voltages V_{A1} , V_{B1} and V_{Cl} , respectively. It is contemplated that once the back EMF voltages at motor terminals 106, 108 and 110 exceed a predetermined value, corresponding bypass contactors 120, 122 and 124, respectively, are sequentially closed such that motor terminal 106 of AC induction AC induction motor 96 is connected directly to AC source 98 through supply line 100, motor terminal 108 of motor 96 is connected directly to AC source 98 through supply line 102, and motor terminal 110 of AC induction motor 96 is connected directly to AC source 98 through supply line 104.

Referring to FIG. 8, in accordance with the present invention, in order to provide increased stability during acceleration of AC induction motor 96, an alternate. approach generally designated by the reference numeral 130 is provided. Thyristor switches 112, 114 and 116 are initially fired at a user selected initial gamma firing angle γ , i.e. 55°, block 132, after each zero supply current therethrough. A preset current limit I_{lim} , block 132, is selected by the user. As pairs of thyristor switches 112, 114 and 116 are sequentially fired at the initial gamma firing angle, γ , the phase currents I_{a1} , I_{b1} and I_{c1} of AC induction motor 96 are determined according to the expression:

$$I = \int_{FT}^{NST} |i(t)| dt$$

wherein I is the integral of the motor current over the previous conduction interval; FT is the initial firing time of the thyristor switches; NST is the next stopping time of the thyristor switches; and i(t) is the instantaneous phase current, block 134.

In order to gradually vary the half cycle time of the thyristor switches 112, 114 and 116, the duration of notch γ in the voltage waveforms V_T is varied with each subsequent firing of thyristor switches 112, 114 and 116 according to expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is the integral of the motor current over the previous conduction interval; and I_{lim} is a user selected pre-set current limit, block 136.

To maintain the stability of AC induction motor 96, it is contemplated that the maximum absolute value of the expression k*(I-I_{lim}) be limited to 0.25°, block 136. Pairs of thyristor switches 112, 114 and 116 are fired again at the new gamma firing angle γ_i after the next zero current crossing of

10

corresponding phase currents I_{a1} , I_{b1} , I_{c1} and the process is repeated until the AC induction motor 12 is at full operating speed, block 138. Once the AC induction motor 96 is at full speed, bypass contactors 120, 122 and 124 are sequentially closed, block 140, such that motor terminals 106, 108 and 110 are connected directly to AC source 98.

It is contemplated that a microprocessor (not pictured) carry out a number of predetermined functions which are incorporated into computer executable instructions, FIG. 8. It should be understood that while these functions are described as being implemented in software, it is contemplated that the functions could be implemented in discreet solid state hardware, as well as, the combination of solid state hardware and software.

It is contemplated that in order to effectuate the methods of the present invention, the microprocessor will include a 15 plurality of inputs corresponding to selected parameters heretofore described. For example, such inputs include line voltages V_{A1} , V_{B1} and V_{C1} line currents I_{A1} , I_{B1} and I_{C1} phase voltages V_{a1} , V_{b1} , and V_{c1} and phase currents I_{a1} , I_{b1} , I_{c1} . Further, it is contemplated that the microprocessor ²⁰ generate a plurality of output signals which correspond to selected instructions heretofore described. For example, referring back to FIG. 6, microprocessor generates firing signals S_{A1} , S_{B1} and S_{C1} to fire corresponding thyristor switches 112, 114, and 116, respectively, at appropriate ²⁵ times, as heretofore described. Similarly, microprocessor generates firing signals B_{A1} , B_{B1} and B_{C1} to close corresponding bypass contactors 120, 122 and 124, respectively, at appropriate times, as heretofore described. 30

Various modes of carrying out the invention are contemplated as being within the scope of the following claims particularly pointing out and distinctly claiming the subject matter which is regarded as the invention.

We claim:

1. A method for controlling a three phase, AC induction ³⁵ motor, each phase of the AC induction motor interconnected to an AC input source by a thyristor switch for providing voltage and current to the AC induction motor, the method comprising the steps of:

- sequentially firing pairs of thyristor switches at an initial gamma firing angle after opening of the thyristor switches, each thyristor switch opening in response to zero current therethrough;
- calculating a new gamma firing angle dependant upon the initial gamma firing angle; and
- sequentially firing pairs of thyristor switches at the new gamma firing angle after opening of the thyristor switches.
- **2**. The method of claim **1** comprising the additional steps $_{50}$ of:
 - providing bypass contactors in parallel across corresponding thyristor switches;
 - monitoring the operating speed of the AC induction motor; and 55
 - closing the bypass contactors in response to the AC induction motor operating at a predetermined operating speed.

3. The method of claim **1** wherein after the step of sequentially firing pairs of thyristor switches at the new $_{60}$ gamma firing angle, executing the additional steps of:

- monitoring the operating speed of the AC induction motor and if the operating speed is less than a predetermined operating speed of the AC induction motor, executing the additional steps of:
 - providing the new gamma firing angle as the initial gamma firing angle; and

65

returning to the step of calculating the new gamma firing angle.

4. A method for controlling the voltage and current supplied to an AC motor, the AC motor interconnected to an AC input source by a thyristor switch, the method comprising the steps of:

- initially firing the thyristor switch at a predetermined gamma firing angle after opening of the thyristor switch and providing the predetermined gamma firing angle as an initial gamma firing angle, the thyristor switch opening in response to zero supply current therethrough;
- calculating a new gamma firing angle which is dependant upon the initial gamma firing angle;
- firing the thyristor switch at the new gamma firing angle after occurrence of zero supply current therethrough; and
- providing the new gamma firing angle as the initial gamma firing angle.

5. The method of claim 4 comprising the additional steps of:

providing a bypass contactor in parallel across the thyristor switch;

monitoring the operating speed of the AC motor; and

closing the bypass contactor in response to the AC motor operating at a predetermined operating speed.

6. The method of claim 4 wherein after the step of firing the thyristor switch at the new gamma firing angle, conducting the additional steps of:

monitoring the operating speed of the AC motor and if the operating speed is less than a predetermined operating speed of the AC motor, executing the additional step of returning to the step of calculating the new gamma firing angle.

7. A method for controlling a three phase, AC induction motor, each phase of the AC induction motor interconnected to an AC input source by a thyristor switch and a bypass contactor connected in parallel for providing voltage and

⁴⁰ current to the AC induction motor, the method comprising the steps of:

- sequentially firing pairs of thyristor switches at a predetermined initial gamma firing angle after opening of the thyristor switches, each thyristor switch opening in response to zero supply current therethrough;
- calculating a new gamma firing angle which is dependant upon the difference between the integral of motor current over a conduction time interval and a user selected pre-set current limit,
- sequentially firing pairs of thyristor switches at the new gamma firing angle after opening of the thyristor switches; and
- monitoring the operating speed of the AC induction motor and if the operating speed is less than a predetermined operating speed of the AC induction motor, executing the additional steps of:
 - providing the new gamma firing angle as the initial gamma firing angle; and
 - returning to the step of calculating the new gamma firing angle.

8. The method of claim 7 comprising the additional step of closing the bypass contactors in response to the AC motor operating at the predetermined operating speed.

9. A method for controlling a three phase, AC induction motor, each phase of the AC induction motor interconnected to an AC input source by a thyristor switch for providing

voltage and current to the AC induction motor, the method comprising the steps of:

- sequentially firing pairs of thyristor switches at an initial gamma firing angle after opening of the thyristor switches, each thyristor switch opening in response to ⁵ zero current therethrough;
- calculating a new gamma firing angle dependant upon the initial gamma firing angle, the new gamma firing angle calculated according to the expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is an integral of the motor current over a conduction time interval; and I_{tim} is a user selected pre-set current limit; and

sequentially firing pairs of thyristor switches at the new gamma firing angle after opening of the thyristor 20 switches.

10. The method of claim 9 comprising the additional steps of comparing the absolute value of the expression $k^*(I-I_{lim})$ to a gamma limit prior to calculating the new gamma firing angle and replacing the expression $k^*(I-I_{lim})$ with the gamma limit in the expression to calculate the new gamma ²⁵ firing angle if the absolute value of the expression $k^*(I-I_{lim})$ is greater than the gamma limit.

11. A method for controlling the voltage and current supplied to an AC motor, the AC motor interconnected to an AC input source by a thyristor switch, the method comprising the steps of:

- initially firing the thyristor switch at a predetermined gamma firing angle after opening of the thyristor switch and providing the predetermined gamma firing angle as ³⁵ an initial gamma firing angle, the thyristor switch opening in response to zero supply current there-through;
- calculating a new gamma firing angle which is dependent upon the initial gamma firing angle, the new gamma 40 firing angle calculated according to the expression:
 - $\gamma_i = \gamma_{i-1} + k^* (I I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the 45 initial gamma firing angle; k is a proportional gain; I is an integral of the motor current over a conduction time interval; and I_{lim} is a user selected pre-set current limit;

firing the thyristor switch at the new gamma firing angle after occurrence of zero supply current therethrough; 50 and providing the new gamma firing angle as the initial gamma firing angle.

12. The method of claim 11 comprising the additional steps of comparing the absolute value of the expression $k^*(I-I_{im})$ to a gamma limit prior to calculating the new gamma firing angle and relating the expression $k^*(I-I_{im})$ with the gamma limit in the expression to calculate the new gamma firing angle if the absolute value of the expression $k^*(I-I_{im})$ is greater than the gamma limit.

13. A method for controlling a three phase, AC induction motor, each phase of the AC induction motor interconnected to an AC input source by a thyristor switch and a bypass contactor connected in parallel for providing voltage and current to the AC induction motor, the method comprising 15 the steps of:

- sequentially firing pairs of thyristor switches at a predetermined initial gamma firing angle after opening of the thristor switches, each thyristor switch opening in response to zero supply current therethrough;
- calculating a new gamma firing angle which is dependent upon the difference between the integral of motor current over a conduction time interval and a user selected pre-set current limit, the new gamma firing angle calculated in accordance to the expression:

 $\gamma_i = \gamma_{i-1} + k^* (I - I_{lim})$

wherein γ_i is the new gamma firing angle; γ_{i-1} is the initial gamma firing angle; k is a proportional gain; I is an integral of the motor current over a conduction time interval; and I_{tim} is a user selected pre-set current limit;

- sequentially firing pairs of thyristor switches at the new gamma firing angle after opening of the thyristor switches; and
- monitoring the operating speed of the AC induction motor and if the operating speed is less than a predetermined operating speed of the AC induction motor, executing the additional steps of:
 - providing the new gamma firing angle as the initial gamma firing angle; and
 - returning the step of calculating the new gamma firing angle.

14. The method of claim 13 comprising the additional steps of comparing the absolute value of the expression $k^*(I-I_{lim})$ to a gamma limit prior to calculating the new gamma firing angle and replacing the expression $k^*(I-I_{lim})$ with the gamma limit in the expression to calculate the new gamma firing angle if the absolute value of the expression $k^*(I-I_{lim})$ is greater than the gamma limit.
